## Overview

Power factor is a measure of how efficiently an AC (alternating current) power system uses the supplied power. It is defined as the ratio of real power (P) to apparent power (S), where the real power is the power. Power factor correction is the process of improving the power factor of a system by adding or removing reactive power sources, such as capacitor banks or synchronous condensers. Power. A capacitor bank works by providing or absorbing reactive power to or from the system, depending on its connection mode and location. There are two main types of capacitor banks: 1. The size of a capacitor bank depends on several factors, such as: 1. The desired power factor improvement or reactive power compensation 2. The voltage level and frequency of. Capacitor banks are useful devices that can store electrical energy and condition the flow of that energy in an electric power system. They can improve the power factor, voltage regulation.

#### Capacitor Bank calculator or kVAR Calculation Formula

Let we calculate the required reactive power in kVAR or capacitor bank to be connected across the motor? Here, PF 1 = 0.7. PF 2 = 0.96. Required capacitor bank =  $100 \times \tan (\cos^{-1} (0.7) - \cos^{-1} (0.96)) = 72.85 \text{ kVAR}$ . Hence you can connect three 25kVAR capacitor bank across the panel for improving the power factor from 0.7 to 0.96
